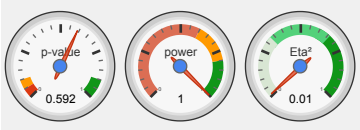
Header: You may change groups' names to the real names.
Data: When entering data, press Enter or , (comma) after each value.
You may paste full column from excel.
The calculator ignores empty cells or non-numeric cells.

Group1 contains 1540 values
Group2 contains 1560 values
validation:success

Hover over the cells for more information.

Source	DF	Sum of Square	Mean Square	F Statistic	P-value
Groups (between groups)	1	0.8606	0.8606	0.2873	0.592
Error (within groups)	3098	9280.0518	2.9955		
Total	3099	9280.9124	2.9948		

R code.



One Way ANOVA test, using F distribution df(1,3098) (right tailed)

1. H_0 hypothesis
Since p-value > α, H_0 is accepted.
The averages of all groups assumed to be equal.
In other words, the difference between the averages of all groups is not big enough to be statistically significant.

2. P-value
p-value equals **0.591986**, [p(x ≤ F) = 0.408014]. It means that if we would reject H_0, the chance of type1 error (rejecting a correct H_0) would be too high: 0.592 (59.2%)
The bigger the p-value the stronger it supports H_0

3. The statistics

Tutorial
ANOVA

Calculators

Kruskal-Wallis test
Two way ANOVA
Levene's test

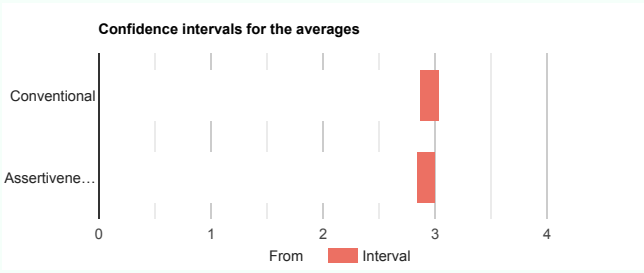
The test statistic F equals **0.287313**, which is in the 95% region of acceptance: [-∞ : 3.8445]

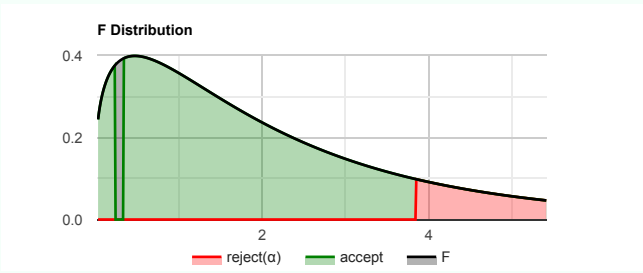
4. Effect size

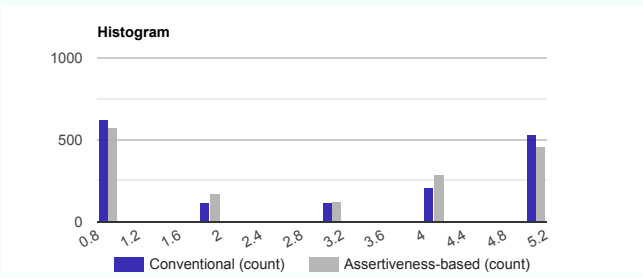
The observed effect size f is **small** (0.0096). That indicates that the magnitude of the difference between the averages is small.
The η^2 equals 0.000093. It means that the **group** explains 0.009% of the variance from the average (similar to R^2 in the linear regression)

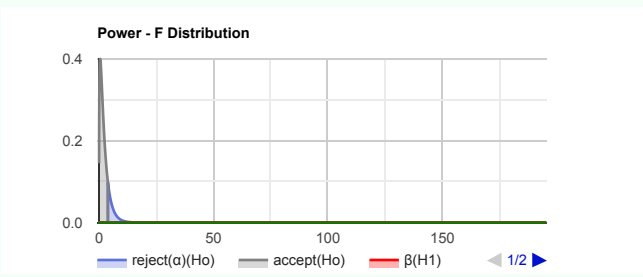
5. Tukey HSD / Tukey Kramer

There is no significant difference between the means of any pair.









Validation

- **Test power**

  The priori power is strong: 1

- **Equality of variances**

  The tool used the Levene's test to assess the equality of variances.
  The population's variances consider to be **not equal**. (p-value = 0.0000151).
  Levene's test power consider to be strong (1).
  The groups' size consider similar. (The ratio between the bigger group and the smaller group is: 1.01)
  The ANOVA test consider to be robust to the homogeneity of variances assumtion when the groups' sizes are similar.

  It is suggested to consider the **Kruskal-Wallis ANOVA.** non-parametric test.

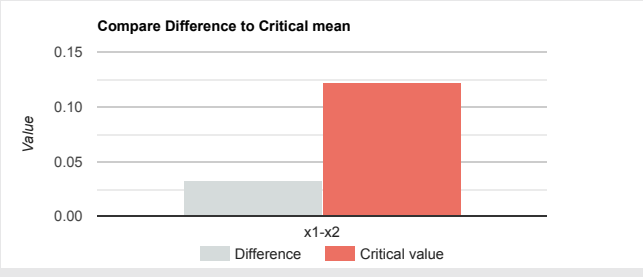
- **Normality assumption**

  The assumption was checked based on the Shapiro-Wilk Test. (α=0.05)
  It is assumed that all the groups distribute normally or have a big sample size, at least 30.

Tukey HSD / Tukey Kramer

Pair	Difference	SE	Q	Lower CI	Upper CI	Critical Mean	p-value
x1-x2	0.03333	0.04396	0.758	-0.08858	0.1552	0.1219	0.592

Group	x2
x1	0.033



ANOVA

What is the ANOVA?

The ANOVA test checks if the difference between the averages of two or more groups is significant, using sample data.
ANOVA is usually used when there are at least three groups since for two groups, the *two-tailed* pooled variance t-test and the *right-tailed* ANOVA test have the same result.
The basic ANOVA test contains only one categorical value, one-way ANOVA. For example, if you compare the performence of three schools, the categorical variable is school, and the possible values of the categorical variable are School-A, School-B, School-C. There are more complex ANOVA tests that contain two categorical variables (Two-way ANOVA calculator), or more. When performing a one-way ANOVA test, we try to determine if the difference between the averages reflects a real difference between the groups, or is due to the random noise inside each group.
The F statistic represents the ratio of the variance between the groups and the variance inside the groups. Unlike many other statistic tests, the smaller the F statistic the more likely the averages are equal.

Example: Compare four fertilizers used in four fields
H_0: The average weight of crops per square meter is equal in all fields.
H_1: At least one field yields a different average per square meter.

Right-tailed, for ANOVA test you can use only the right tail. Why?

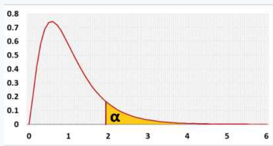
Hypotheses

H_0: $\mu_1 = ... = \mu_k$
H_1: not($\mu_1 = ... = \mu_k$)

ANOVA formula

$$F = \frac{MSG}{MSE}$$

F distribution



Assumptions

- Independent samples
- Normal distribution of the analyzed population
- Equal standard deviation, $\sigma_1=\sigma_2=...=\sigma_k$
  The assumption is more important when the groups' sizes not similar

Required Sample Data

- Sample data from all compared groups

Parameters

- **k** - Number of groups.
- **n_i** - Sample side of group i
- **n** - Overall sample side, includes all the groups (Σn_i, i=1 to k)
- **$\bar{x}_i$** - Average of group i.
- **$\bar{x}$** - Overall average ($\Sigma x_{i,j}$ / n, i=1 to k, j=1 to n_i)
- **S_i** - Standard deviation of group i

Results calculations

Source	Degrees of Freedom	Sum of Squares	Mean Square	F statistic	p-value
Groups (between groups)	k - 1	$SSG=\sum_{i=1}^{k} n_i\,(\bar{x}_i-\bar{x})^2$	MSG = SSG / (k - 1)	F = MSG / MSE	P(x > F)
Error (within groups)	n - k	$SSE=\sum_{i=1}^{k}(n_i-1)\,S_i^2$	MSE = SSE / (n - k)		
Total	n - 1	SS(total) = SSG + SSE	Sample Variance = SS(total) / (n - 1)		

R Code

The following R code should produce the same results

```
value0 <-
c(1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,
