Source	DF	Sum of Square	Mean Square	F Statistic	P-value
Groups (between groups)	1	11.7135	11.7135	2.4727	0.1179
Error (within groups)	154	729.5171	4.7371		
Total	155	741.2306	4.7821		

[R code.](#)

One Way ANOVA test, using F distribution df(1,154). (right tailed).

1. H₀ hypothesis

Since p-value > α , H₀ is accepted.
The averages of all groups assumed to be equal.
In other words, the difference between the averages of all groups is not big enough to be statistically significant.

2. P-value

p-value equals **0.117891**, [p($x \leq F$) = 0.882109]. It means that if we would reject H₀, the chance of type1 error (rejecting a correct H₀) would be too high: 0.1179 (11.79%)
The bigger the p-value the stronger it supports H₀

3. The statistics

The test statistic F equals **2.472707**, which is in the 95% region of acceptance: [- ∞ : 3.9026]

4. Effect size

The observed effect size f is **small** (0.13). That indicates that the magnitude of the difference between the averages is small.
The η^2 equals 0.016. It means that the **group** explains 1.6% of the variance from the average (similar to R² in the linear regression)

5. Tukey HSD / Tukey Kramer

There is no significant difference between the means of any pair.

Validation

Test power

The priori power is strong: 0.8735

Equality of variances

The tool used the Levene's test to assess the equality of variances.
The population's variances consider to be **equal**. (p-value = 0.0926).
Levene's test power consider to be strong (0.87).
The groups' size consider similar. (The ratio between the bigger group and the smaller group is: 1.26)
The ANOVA test consider to be robust to the homogeneity of variances assumption when the groups' sizes are similar.

Normality assumption

The assumption was checked based on the [Shapiro-Wilk Test](#). (α=0.05)
It is assumed that all the groups distribute normally or have a big sample size, at least 30.

Tukey HSD / Tukey Kramer

Pair	Difference	SE	Q	Lower CI	Upper CI	Critical Mean	p-value
x1-x2	0.5517	0.2481	2.2238	-0.1414	1.2448	0.6931	0.1179

Group	x2
x1	0.55

ANOVA

What is the ANOVA?

The ANOVA test checks if the difference between the averages of two or more groups is significant, using sample data.
ANOVA is usually used when there are at least three groups since for two groups, the *two-tailed* pooled variance t-test and the *right-tailed* ANOVA test have the same result.
The basic ANOVA test contains only one categorical value, one-way ANOVA. For example, if you compare the performance of three schools, the categorical variable is school, and the possible values of the categorical variable are School-A, School-B, School-C. There are more complex ANOVA tests that contain two categorical variables ([Two-way ANOVA calculator](#)), or more. When performing a one-way ANOVA test, we try to determine if the difference between the averages reflects a real difference between the groups, or is due to the random noise inside each group.
The F statistic represents the ratio of the variance between the groups and the variance inside the groups. Unlike many other statistic tests, the smaller the F statistic the more likely the averages are equal.

Example: Compare four fertilizers used in four fields
H₀: The average weight of crops per square meter is equal in all fields.
H₁: At least one field yields a different average per square meter.

Right-tailed, for ANOVA test you can use only the right tail. [Why?](#)

Hypotheses

H₀: μ₁ = ... = μ_k
H₁: not(μ₁ = ... = μ_k)

ANOVA formula

$$F = \frac{MSG}{MSE}$$

F distribution

An F distribution curve plot. The x-axis ranges from 0 to 6, and the y-axis ranges from 0 to 0.8. The area under the curve to the right of a critical value is shaded yellow and labeled α.

- Independent samples
- Normal distribution of the analyzed population
- Equal standard deviation, $\sigma_1=\sigma_2=...=\sigma_k$

The assumption is more important when the groups' sizes not similar

- Sample data from all compared groups

- k - Number of groups.
- n_i - Sample side of group i
- n - Overall sample side, includes all the groups ($\sum n_i, i=1$ to k)
- \bar{x}_i - Average of group i .
- \bar{x} - Overall average ($\sum x_{i,j} / n, i=1$ to $k, j=1$ to n_i)
- S_i - Standard deviation of group i

Source	Degrees of Freedom	Sum of Squares	Mean Square	F statistic	p-value
Groups (between groups)	$k - 1$	$SSG = \sum_{i=1}^k n_i (\bar{x}_i - \bar{x})^2$	$MSG = SSG / (k - 1)$	$F = MSG / MSE$	$P(x > F)$
Error (within groups)	$n - k$	$SSE = \sum_{i=1}^k (n_i - 1) S_i^2$	$MSE = SSE / (n - k)$		
Total	$n - 1$	$SS(\text{total}) = SSG + SSE$	$\text{Sample Variance} = SS(\text{total}) / (n - 1)$		

The following R code should produce the same results

[illegible]
